### MergingDataFrame\_ed

### May 17, 2022

In this lecture we're going to address how you can bring multiple dataframe objects together, either by merging them horizontally, or by concatenating them vertically. Before we jump into the code, we need to address a little relational theory and to get some language conventions down. I'm going to bring in an image to help explain some concepts.

### 6: Venn Diagram

Venn Diagram

Ok, this is a Venn Diagram. A Venn Diagram is traditionally used to show set membership. For example, the circle on the left is the population of students at a university. The circle on the right is the population of staff at a university. And the overlapping region in the middle are all of those students who are also staff. Maybe these students run tutorials for a course, or grade assignments, or engage in running research experiments.

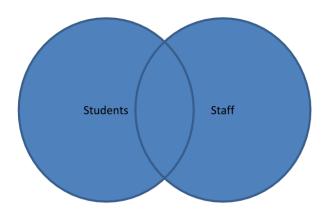

So, this diagram shows two populations whom we might have data about, but there is overlap between those populations.

When it comes to translating this to pandas, we can think of the case where we might have these two populations as indices in separate DataFrames, maybe with the label of Person Name.

When we want to join the DataFrames together, we have some choices to make. First what if we want a list of all the people regardless of whether they're staff or student, and all of the information we can get on them? In database terminology, this is called a full outer join. And in set theory, it's called a union. In the Venn diagram, it represents everyone in any circle.

Here's an image of what that would look like in the Venn diagram.

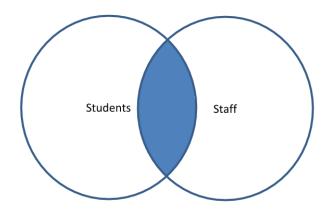

# 7: Full outer join (union)

Union

It's quite possible though that we only want those people who we have maximum information for, those people who are both staff and students. Maybe being a staff member and a student involves getting a tuition waiver, and we want to calculate the cost of this. In database terminology, this is called an inner join. Or in set theory, the intersection. It is represented in the Venn diagram as the overlapping parts of each circle.

## 7: Inner join (intersection)

#### Here's what that looks like:

```
[1]: # With that background, let's see an example of how we would do this in pandas,
    →where we would use the merge
    # function.
   import pandas as pd
   # First we create two DataFrames, staff and students.
   staff_df = pd.DataFrame([{'Name': 'Kelly', 'Role': 'Director of HR'},
                             {'Name': 'Sally', 'Role': 'Course liasion'},
                             {'Name': 'James', 'Role': 'Grader'}])
   # And lets index these staff by name
   staff_df = staff_df.set_index('Name')
   # Now we'll create a student dataframe
   student_df = pd.DataFrame([{'Name': 'James', 'School': 'Business'},
                               {'Name': 'Mike', 'School': 'Law'},
                               {'Name': 'Sally', 'School': 'Engineering'}])
   # And we'll index this by name too
   student_df = student_df.set_index('Name')
   # And lets just print out the dataframes
   print(staff_df.head())
   print(student_df.head())
```

Role

Name
Kelly Director of HR
Sally Course liasion
James Grader

School

Name

James Business
Mike Law
Sally Engineering

- [2]: # There's some overlap in these DataFrames in that James and Sally are both

  → students and staff, but Mike and

  # Kelly are not. Importantly, both DataFrames are indexed along the value we

  → want to merge them on, which is

  # called Name.
- [3]: # If we want the union of these, we would call merge() passing in the DataFrame\_\_\_\_\_\_ on the left and the DataFrame

  # on the right and telling merge that we want it to use an outer join. We want\_\_\_\_\_\_ to use the left and right

  # indices as the joining columns.

  pd.merge(staff\_df, student\_df, how='outer', left\_index=True, right\_index=True)
- [3]: Role School
  Name
  James Grader Business
  Kelly Director of HR NaN
  Mike NaN Law
  Sally Course liasion Engineering
- [4]: # We see in the resulting DataFrame that everyone is listed. And since Mike\_
   does not have a role, and John

  # does not have a school, those cells are listed as missing values.

  # If we wanted to get the intersection, that is, just those who are a student\_
   AND a staff, we could set the

  # how attribute to inner. Again, we set both left and right indices to be true\_
   as the joining columns

  pd.merge(staff\_df, student\_df, how='inner', left\_index=True, right\_index=True)
- [4]: Role School
  Name
  Sally Course liasion Engineering
  James Grader Business
- [5]: # And we see the resulting DataFrame has only James and Sally in it. Now there

  → are two other common use cases

  # when merging DataFrames, and both are examples of what we would call set

  → addition. The first is when we

  # would want to get a list of all staff regardless of whether they were

  → students or not. But if they were

```
# students, we would want to get their student details as well. To do this well
     →would use a left join. It is
    # important to note the order of dataframes in this function: the first \Box
    → dataframe is the left dataframe and
    # the second is the right
    pd.merge(staff_df, student_df, how='left', left_index=True, right_index=True)
[5]:
                     Role
                                School
   Name
   Kelly Director of HR
          Course liasion
    Sally
                          Engineering
    James
                   Grader
                              Business
[6]: # You could probably guess what comes next. We want a list of all of the
     ⇒students and their roles if they were
    # also staff. To do this we would do a right join.
    pd.merge(staff_df, student_df, how='right', left_index=True, right_index=True)
[6]:
                     Role
                                School
    Name
    James
                   Grader
                              Business
    Mike
                      NaN
                                    Law
    Sally Course liasion Engineering
[7]: # We can also do it another way. The merge method has a couple of other
    →interesting parameters. First, you
    # don't need to use indices to join on, you can use columns as well. Here's an
     →example. Here we have a
    # parameter called "on", and we can assign a column that both dataframe has as \Box
     → the joining column
    # First, lets remove our index from both of our dataframes
    staff df = staff df.reset index()
    student_df = student_df.reset_index()
    # Now lets merge using the on parameter
    pd.merge(staff_df, student_df, how='right', on='Name')
[7]:
       Name
                        Role
                                   School
    O Sally Course liasion Engineering
    1 James
                      Grader
                                  Business
       Mike
                         NaN
                                       Law
[8]: # Using the "on" parameter instead of a the index is how I find myself using \Box
     \rightarrowmerge() the most.
[9]: # So what happens when we have conflicts between the DataFrames? Let's take a_{\sqcup}
     → look by creating new staff and
    # student DataFrames that have a location information added to them.
```

```
staff_df = pd.DataFrame([{'Name': 'Kelly', 'Role': 'Director of HR',
                                'Location': 'State Street'},
                              {'Name': 'Sally', 'Role': 'Course liasion',
                                'Location': 'Washington Avenue'},
                              {'Name': 'James', 'Role': 'Grader',
                               'Location': 'Washington Avenue'}])
     student_df = pd.DataFrame([{'Name': 'James', 'School': 'Business',
                                 'Location': '1024 Billiard Avenue'},
                                {'Name': 'Mike', 'School': 'Law',
                                 'Location': 'Fraternity House #22'},
                                {'Name': 'Sally', 'School': 'Engineering',
                                 'Location': '512 Wilson Crescent'}])
     # In the staff DataFrame, this is an office location where we can find the \Box
     ⇒staff person. And we can see the
     # Director of HR is on State Street, while the two students are on Washington
     → Avenue, and these locations just
     # happen to be right outside my window as I film this. But for the student
      → DataFrame, the location information
     # is actually their home address.
     # The merge function preserves this information, but appends an x or y to
     →help differentiate between which
     # index went with which column of data. The _x is always the left DataFrame_
     \rightarrow information, and the \_y is always
     # the right DataFrame information.
     # Here, if we want all the staff information regardless of whether they were
     ⇔students or not. But if they were
     # students, we would want to get their student details as well. Then we can do a_{\sqcup}
     →left join and on the column of
     # Name
     pd.merge(staff_df, student_df, how='left', on='Name')
[9]:
        Name
                         Role
                                                        School
                                      Location_x
                                                                          Location_y
     O Kelly Director of HR
                                    State Street
                                                           NaN
                                                                                 NaN
     1 Sally Course liasion Washington Avenue Engineering
                                                                 512 Wilson Crescent
     2 James
                       Grader Washington Avenue
                                                     Business 1024 Billiard Avenue
[10]: # From the output, we can see there are columns Location_x and Location_y. \Box
     →Location_x refers to the Location
     # column in the left dataframe, which is staff dataframe and Location_y refers_{\sqcup}
     →to the Location column in the
     # right dataframe, which is student dataframe.
```

```
# Before we leave merging of DataFrames, let's talk about multi-indexing and
      →multiple columns. It's quite
     # possible that the first name for students and staff might overlap, but the
     → last name might not. In this
     # case, we use a list of the multiple columns that should be used to join keys_{\sqcup}
     → from both dataframes on the on
     \# parameter. Recall that the column name(s) assigned to the on parameter needs<sub>\sqcup</sub>
      →to exist in both dataframes.
     # Here's an example with some new student and staff data
     staff_df = pd.DataFrame([{'First Name': 'Kelly', 'Last Name': 'Desjardins',
                                'Role': 'Director of HR'},
                               {'First Name': 'Sally', 'Last Name': 'Brooks',
                                'Role': 'Course liasion'},
                               {'First Name': 'James', 'Last Name': 'Wilde',
                                'Role': 'Grader'}])
     student_df = pd.DataFrame([{'First Name': 'James', 'Last Name': 'Hammond',
                                  'School': 'Business'},
                                 {'First Name': 'Mike', 'Last Name': 'Smith',
                                  'School': 'Law'},
                                 {'First Name': 'Sally', 'Last Name': 'Brooks',
                                  'School': 'Engineering'}])
     # As you see here, James Wilde and James Hammond don't match on both keys since
      → they have different last
     # names. So we would expect that an inner join doesn't include these_
     →individuals in the output, and only Sally
     # Brooks will be retained.
     pd.merge(staff_df, student_df, how='inner', on=['First Name','Last Name'])
[10]: First Name Last Name
                                        Role
                                                   School

                     Brooks Course liasion Engineering
[11]: \parallel Joining dataframes through merging is incredibly common, and you'll need to
     →know how to pull data from
     # different sources, clean it, and join it for analysis. This is a staple not_{\sqcup}
     →only of pandas, but of database
     # technologies as well.
[12]: | # If we think of merging as joining "horizontally", meaning we join on similar
      →values in a column found in two
     # dataframes then concatenating is joining "vertically", meaning we put !!
     \hookrightarrow dataframes on top or at the bottom of
     # each other
     # Let's understand this from an example. You have a dataset that tracks some
      → information over the years. And
```

```
→ has the exactly same columns.
     # What happens if you want to put all the data, from all years' record,
      → together? You can concatenate them.
[13]: # Let's take a look at the US Department of Education College Scorecard data It_{\sqcup}
      →has each US university's data
     # on student completion, student debt, after-graduation income, etc. The data__
      →is stored in separate CSV's with
     # each CSV containing a year's record Let's say we want the records from 2011_
      →to 2013 we first create three
     # dataframe, each containing one year's record. And, because the csv files
      \rightarrowwe're working with are messy, I
     # want to supress some of the jupyter warning messages and just tell read csv_{\sqcup}
      \hookrightarrow to ignore bad lines, so I'm
     # going to start the cell with a cell magic called %%capture
 [3]: %%capture #para que no se impriman los errores al abrir los archivos .csv

```
[30832 rows x 1977 columns]
[18]: # As you can see, we have more observations in one dataframe and columns remain
             \hookrightarrow the same. If we scroll down to
            # the bottom of the output, we see that there are a total of 30,832 rows after
             → concatenating three dataframes.
            # Let's add the number of rows of the three dataframes and see if the two_{\sqcup}
              →numbers match
            len(df_2011)+len(df_2012)+len(df_2013)
[18]: 30832
[19]: # The two numbers match! Which means our concatenation is successful. But wait,
             →now that all the data is
            # concatenated together, we don't know what observations are from what year was a second to the seco
              →anymore! Actually the concat
            # function has a parameter that solves such problem with the keys parameter, we well
              →can set an extra level of
            # indices, we pass in a list of keys that we want to correspond to the
             → dataframes into the keys parameter
            # Now let's try it out
            pd.concat(frames, keys=['2011','2012','2013'])

                                                                        NaN
```

#### [30832 rows x 1977 columns]

```
[20]: # Now we have the indices as the year so we know what observations are from what year. You should know that

# concatenation also has inner and outer method. If you are concatenating two dataframes that do not have

# identical columns, and choose the outer method, some cells will be NaN. If you choose to do inner, then some

# observations will be dropped due to NaN values. You can think of this as analogous to the left and right

# joins of the merge() function.
```

Now you know how to merge and concatenate datasets together. You will find such functions very useful for combining data to get more complex or complicated results and to do analysis with. A solid understanding of how to merge data is absolutely essentially when you are procuring, cleaning, and manipulating data. It's worth knowing how to join different datasets quickly, and the different options you can use when joining datasets, and I would encourage you to check out the pandas docs for joining and concatenating data.
